92) Which date structure are used to implement BFS and DFS and why? - For implementing BFs we need a greene date structure for finding shortest path between any node. We use queue because things in FIFO order like BFS: BFS searches for nades level wee, it it searches nodes wirit their distance from root (source). For this queue is letter to use in BFS. For implementing DFS me need a stack data structure as it transcress a graph in depthemand metion and uses stack to remember to get the next vertex to start a search, when a dead end occurs in any iteration. 93) What do you mean by sparse and dense graphs? Which representation of graph is better for opense and dense graph? La Dense graph is a graph in which no of edges is close to maximal no of edges. Eparse graph is graph in which no of edges is very less. (many edges b/w nedes) Sparse graphs (few edges For sparse graph it is preferred to use Adjacency Matrix.

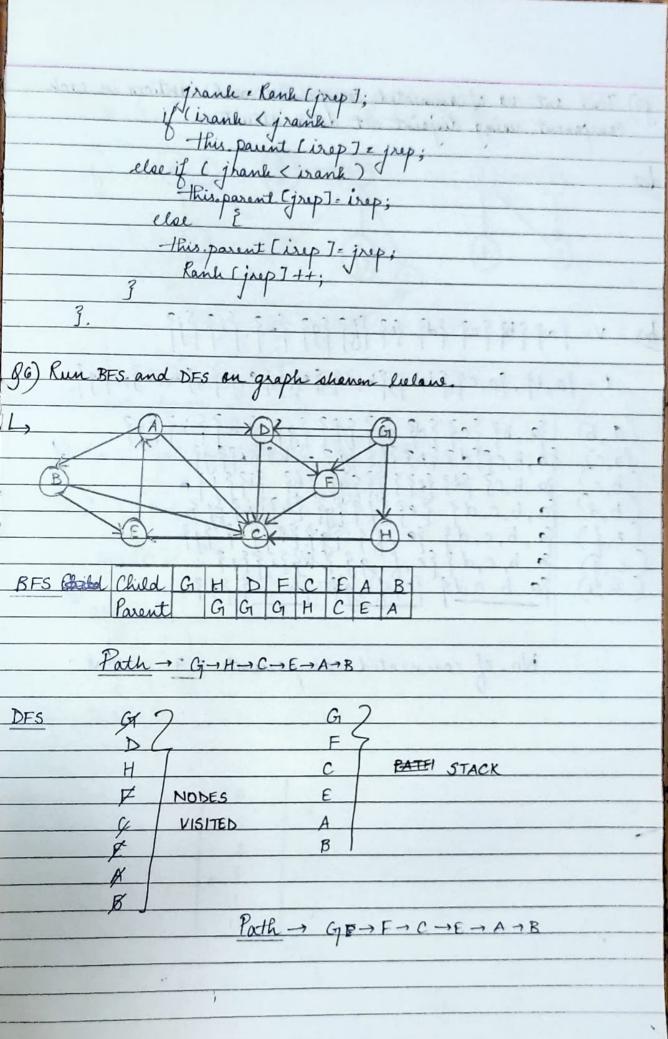

94) How can you detect a cycle in a graph using BFS and DFS? Ans. For detecting cycle in a graph wing BF5 we need to use Kahn's algorithm for Topological Garting— The steps involved are: Decrease in-degree by 1 for all its neighbouring nodes.

Thin-degree of neighbouring nodes is reduced to zero then add to queue. 4) Repeat 3) until quene is empty.

5) It count of moited nodes is not equal to no. of nodes in graph, has cycle, otherwise not For delecting cycle in graph using DEs we need to dayfollowing:

DES for a connected graph produces a tree. There is cycle in graph if there is a lock edge present in the graph. A back edge is an edge that is from a node to itself (self-loop) or one of its ancesters in the tree produced by DFS. For a disconnected graph, get According back edges To detect a leach edge, heep track of western currently for DFS transreal. If a vertex is reached that is already in recurrent stack, then there is a cycle: 35) What do you mean by disjoint set data structure? Explain 3
coperations along with examples which can be performed on
disjoint sets? Any A disjoint out in a data structure that keeps track of set of elements partiened into several disjoint sets subsets. In other mands, a disjoint set is a group of sets where no item can be in more than

3 operations:
Find - can be implemented by recureively traversing the parent array until we hit a node who is parent to itself. eg. int find (int i) f if (parent I i] == i) f return i;
dray until we lit a nade who is parent to itself.
bil (Int 1) F
parent [i] == i)
return i;
6 1964 att white points in the said the said to
else s
return find (parent [i]);
3 and a super as whose a more desired as a super in the
sets using the find operation and finally puts either one of the trees under root nade of other tree, effectively merging the trees and sets.
sets using the find operation and finally puts either one of the
trees under root nade of other tree, effectively marging the trus
and sets.
eg: void union (inti, int j) ?
eg: void union (int i, int j) f int irep = this. Find (i);
int jrep = this. Find (j); this. parent [irep] = jrep;
This parent Cirep] = jrep,
degrapping by a failet a sulent for delast such . Cheek his sulent
Union by Rank -> We need a new array rank []. Sice of array same as
farmer assay. of its representative of set, rank lit is height of tree.
We her somewhite height of tree of we are uniting 2 trees, we
call them left and right, then it all depends on rank of left and right
· If rank of left is less than right then it's less to move left under right
The way were the start of the s
sanks are equal, rank of result will always be one greater than
you winen (inti, intj) {
till P. T. I(i)
ent jup: thue find (j);
(1 rep 20 jrep) return;
iranlie Rank L'irap 7;

87) Find out no of connected components and vertices in each
97) Find out no of connected components and vertices in each component using disjoint set data structure.

Mame few graph algorithm where you need to use priority quene queue and why? fur. Is, heap data structure can be used to implement priority greve. It will take O (log N) time to insert and do cate each element in priority greve. Based on heap structure, priority greve has two types max-priority grove based on max heap and min probity greve based on min-heap. Heaps provide better performance comparison to away Ef Lol. The graphs like Dijhotra's Shortest path algorithm, Prim's Minimum Spanning Tree use Priority Guere. existera's Algorithm - When graph is stored in form of adjacency lest or matrix, priority queue is used to extract minimum Officiently when implementing the algorithm. Trim's Agorithm - It is used to store keys of node's and extract minimum key node at every step. g10) Sifferentiate between Min-heap and Max-heap. L> Min-Heap Max-heap of max-heap the keypresent at root In min heap, key present at root nade unde must be greater than or equal to must be less than or equal to among keys present at all of its children. among heys present at all of its children.
